## Summary

Pedigree visualization is essential across multiple research disciplines, including human genetics, animal breeding, genealogical research, forensic science, and counseling. Human geneticists use pedigree diagrams to trace disease inheritance patterns and identify at-risk individuals in families affected by genetic disorders. Animal breeders rely on pedigree visualization to track lineages, plan breeding programs, and optimize genetic traits across generations of livestock and crops. Genealogical researchers use family trees to document ancestral relationships and explore heritage, while forensic scientists analyze pedigree structures to establish familial connections in criminal investigations. Family therapists and counselors use genograms to visualize family dynamics, relationship patterns, and psychological factors across generations to inform therapeutic interventions.

Traditional pedigree plotting tools such as `kinship2` (?) have served these communities well for basic family structures.

Recently, these fields have expanded to analyze increasingly complex family structures, including large-scale plant breeding pedigrees (?), web-based pedigree management systems (?), interactive pedigree editors (?), and behavior genetic studies of extended family structures ([Garrison et al., 2023](#); [Hunter, Garrison, Burt, & Rodgers, 2021](#)). These developments have highlighted the limitations of existing pedigree visualization tools, which often struggle to handle large datasets and complex relationships.

`ggpedigree` simplifies the visualization of these complex family structures by offering a comprehensive suite of functions for creating publication-quality pedigree plots of any size and complexity.

## Statement of need

Pedigree visualization has traditionally relied on specialized proprietary software (like ) or R packages like `kinship2` ([Sinnwell, Therneau, & Schaid, 2014](#)) or `pedtricks`, which generate static plots using base graphics and minimal layout control. While these tools are functional for small, nuclear pedigrees, their limitations become pronounced when working with complex, modern pedigree datasets. First, base R graphics lack the modular design and extensibility needed for generating publication-quality pedigree figures. Second, most existing R-based tools offer no interactivity, making it difficult to explore large pedigrees dynamically. Third, current solutions are poorly integrated with tidyverse workflows and do not produce `ggplot2`-based objects that users can customize or extend (?).

Recent advances in behavior genetics and genetic epidemiology ([Garrison et al., 2023](#); [McArdle & McDonald, 1984](#)) have introduced new visualization demands, particularly for extended families and highly interconnected pedigrees. Modern pedigree datasets can include hundreds

or thousands of individuals across multiple generations, with overlapping relationships, consanguinity, remarriages, and twin sets that strain existing layout algorithms. Additionally, researchers increasingly need to overlay phenotypic information, genetic relatedness values, and model outputs onto pedigree plots to support interpretation and communication of their findings.

Several R packages attempt to address these challenges with built-in pedigree plotting functions. `kinship2` (Sinnwell et al., 2014) remains widely used but produces static base graphics and relies on non-vectorized recursive layout functions that does not scale well to large families. A partial `ggplot2` implementation exists but is incomplete, non-vectorized, and not actively maintained. The `geneHapR` (Zhang, Jia, & Diao, 2023) package focuses on haplotype visualization rather than general pedigree structure. The `pedgene` package provides some plotting functions but is primarily designed for association testing. None of these packages offers the combination of modern `ggplot2` integration, interactive capabilities, and extensibility that `ggpedigree` provides. `ggpedigree` addresses these limitations by providing a comprehensive visualization framework built on modern R graphics infrastructure. It leverages the extensive customization capabilities of `ggplot2` while adding specialized functionality for pedigree-specific visualization challenges.

## Software Architecture

`ggpedigree` is built on a modular architecture that separates data processing, layout calculation, and visualization layers. The core workflow involves: (1) data standardization and family structure analysis using `BGmisc` functions, (2) coordinate calculation using algorithms adapted from `kinship2`, (3) relationship connection mapping, and (4) layer-based plot construction using `ggplot2` geometry functions. This design allows users to customize any aspect of the visualization while maintaining computational efficiency for large pedigrees. The package integrates tightly with the broader R ecosystem, particularly the `tidyverse` (?) and `BGmisc` (Garrison, S. Mason, Hunter, Michael D., Lyu, Xuanyu, Trattner, Jonathan D., & Burt, S. Alexandra, 2024). All functions return standard R objects (`ggplot` or `plotly`) that can be further customized using familiar syntax, ensuring accessibility for users already comfortable with modern R data science workflows.

## Features

The `ggpedigree` package offers comprehensive visualization capabilities organized into several main categories:

### Pedigree Visualization and Customization

- **Data Standardization and Family Structure Analysis:** `ggPedigree()` integrates with `BGmisc` functions like `ped2fam()` to organize individuals by family, `recodeSex()` to standardize sex coding, and `checkParentIDs()` to validate pedigree structures. The function handles complex scenarios including consanguineous relationships and individuals appearing in multiple pedigree positions.
- **Coordinate Calculation:** `calculateCoordinates()` computes optimal positioning for individuals using algorithms adapted from `kinship2::align.pedigree`, with enhancements for large multi-generational pedigrees and complex family structures. The function returns coordinate grids that optimize spacing and minimize visual overlap. These steps are vectorized as much as possible to ensure computational efficiency, especially for large pedigrees.
- **Relationship Connection Mapping:** `calculateConnections()` generates connection paths between family members, mapping parent-child, sibling, spousal, and twin relationships. The function determines midpoints for line intersections and handles overlapping connections with specialized curved segments. These calculations are optimized for large

87 datasets by using vectorized operations rather than the loop-based approaches used in  
88 kinship2.

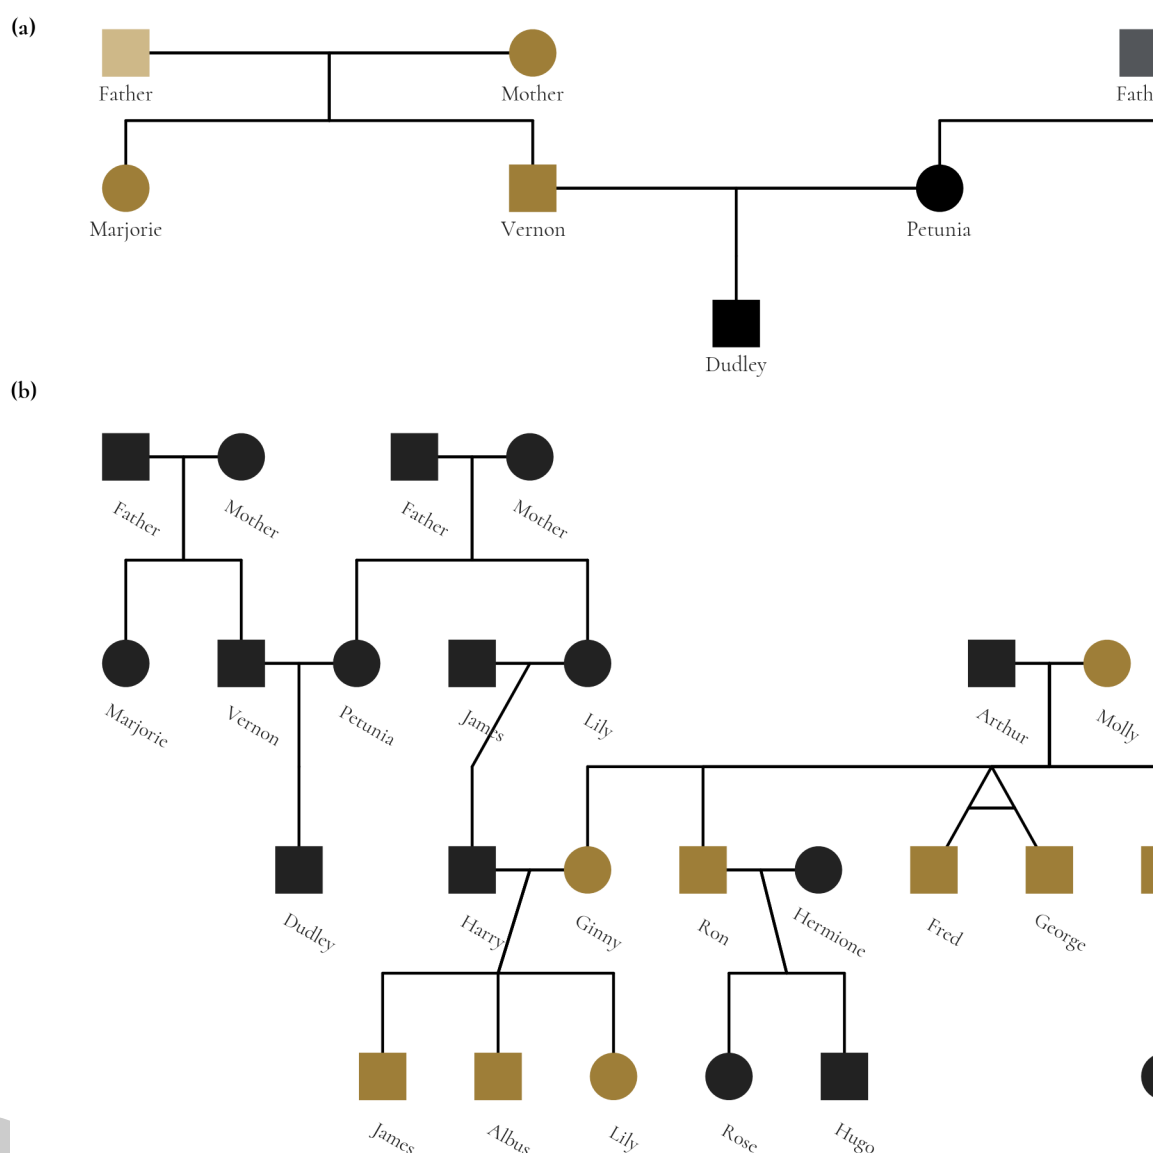

- 89 ■ Layer-based Plot Construction: `ggPedigree()` constructs plots using `ggplot2` geometry  
90 functions, returning standard `ggplot2` objects that integrate with existing R workflows.  
91 `ggPedigreeInteractive()` extends plots into interactive `plotly` widgets with hover tooltips  
92 and dynamic exploration capabilities. A comprehensive config system allows customization  
93 of over 100 aesthetic and layout parameters.
- 94 ■ Focal Individual Highlighting: Advanced functionality to highlight specific individuals and  
95 their relatives based on additive genetic, mitochondrial, or other relationship matrices.

## 96 Specific Visualizations

- 97 ■ Pedigree Plotting: `ggPedigree()` creates static pedigree plots using `ggplot2`, supporting  
98 complex family structures, multiple generations, and customizable aesthetics. It can  
99 handle large pedigrees with thousands of individuals while maintaining clarity and  
100 readability.
- 101 ■ Interactive Pedigree Visualization: `ggPedigreeInteractive()` generates interactive pedi-  
102 gree plots using `plotly`, allowing users to explore large pedigrees dynamically. Users can  
103 configure tooltip content to display individual IDs, names, phenotypic information, and  
104 other relevant data. It supports tooltips, zooming, and panning for detailed exploration  
105 of family structures.
- 106 ■ Relatedness Matrix Heatmaps: `ggRelatednessMatrix()` creates customizable heatmap  
107 visualizations for genetic relatedness matrices with support for hierarchical clustering,  
108 interactive exploration, and seamless integration with `BGmisc` relatedness calculations.
- 109 ■ Phenotype-Relatedness Analysis: `ggPhenotypeByDegree()` produces specialized plots  
110 for visualizing phenotypic correlations as a function of genetic relatedness, including  
111 confidence intervals and statistical summaries for quantitative genetic analysis.

## 112 Illustrative Examples

113 Here we illustrate some of the features by reproducing the figure from Hunter, Garrison,  
114 et al 2025 but restyled it to conform to the Wake Forest Style Guidelines. As you can  
115 see, the `ggpedigree` package allows for complex family structures to be visualized in a clear  
116 and aesthetically pleasing manner. The plot includes individuals' names, relationships, and  
117 phenotypic information, all while maintaining clarity even with overlapping relationships.  
118 Although pleasing, this level of customization is not required, as default settings produce clear  
119 and informative pedigree plots.

Collectively, these tools provide a valuable resource for behavior geneticists and others who work with extended family data. They were developed as part of a grant and have been used in several ongoing projects and forthcoming papers (Burt, 2023; Garrison et al., 2023; Hunter et al., 2023; Lyu et al., 2023) and theses (Lyu, 2023).

## Availability

The ggpedigree package is open-source and available on both GitHub at <https://github.com/R-Computing-Lab/ggpedigree> and the Comprehensive R Archive Network (CRAN) at <https://cran.r-project.org/package=ggpedigree>. It is licensed under the GNU General Public License.

## Acknowledgments

The current research is supported by the National Institute on Aging (NIA), RF1-AG073189. The authors would like to thank Michael Hunter for their support and enthusiasm to the development of this package.
